Abstract

Seven new species of *Argia* are described, five of which occur in Costa Rica: *Argia calverti* n. sp. (Holotype ♂, Costa Rica, Cartago Prov., Tapantí Reserve, 1,310 m, 6 vii 1963, F. G. Thompson leg., in FSCA); *Argia carolus* n. sp. (Holotype ♂, Costa Rica, San José Prov., El Rodeo Biological Reserve, 7 km W of Villa Colón, 9°54' N, 84°16' W, 561 m, 10–13 vii 1990, T. W. Donnelly leg., in FSCA); *Argia elongata* n. sp. (Holotype ♂, Costa Rica, Cartago Prov., Reventazón river, SE of Turrialba by highway 10, 9°52'56" N, 83°38'49" W, 561 m, 10 viii 1979, R. W. & J. A. Garrison leg., in CSCA); *Argia haberri* n. sp. (Holotype ♂, Costa Rica, San José Prov., Bosque del Tolomuco, km 118 on Pan American highway, in seeps and trickles through brushy pasture on forested hillside, 9°28'18" N, 83°41'48" W, 1,710 m, 27 iii 2006, F. Sibley leg., in FSCA); *Argia schorri* n. sp. (Holotype ♂, Costa Rica, Puntarenas Prov., 2.8 mi E of Golfito, 8°39' N, 83°7' W, 35 m, 4 vii 1967, O. S. Flint, Jr. & M. A. Ortiz B. leg., in USNM), and two which are so far only known from Mexico and Ecuador respectively: *Argia rudolphi* n. sp. (Holotype ♂, Mexico, Puebla State, Zihuateutla, Sierra de Huachinango, La Unión, in drainage area, 20°14'25" N, 97°53'38" W, 596 m, 21 v 1987, R. Novelo & A. Gómez leg., in CSCA) and *Argia schneideri* n. sp. (Holotype ♂, Ecuador, Napo Prov., Las Palmas, on Anzu river in Napo river watershed, 11 xii 1936, W. Clark-MacIntyre leg., in UMMZ). All the new species, as well as closely related species needed for diagnosis including *A. anceps* Garrison, *A. cupraurea* Calvert, *A. cuprea* (Hagen), *A. extranea* (Hagen), *A. fissa* Selys, *A. fulgida* Navás, *A. oenea* Hagen in Selys, *A. popoluca* Calvert, *A. rhoadsi* Calvert, and *A. westfalli* Garrison, are illustrated and diagnosed from their congeners and their known distribution areas are mapped.

Key words: Damselfly, Neotropics, new species, diagnoses, distribution maps

Resumen

Siete nuevas especies de *Argia* son descriptas, cinco de las cuales ocurren en Costa Rica: *Argia calverti* n. sp. (Holotipo ♂, Costa Rica, Cártago Prov., Reserva Tapantí, 1,310 m, 6 vii 1963, F. G. Thompson leg., en FSCA); *Argia carolus* n. sp. (Holotipo ♂, Costa Rica, San José Prov., Reserva Biológica El Rodeo, 7 km O de Villa Colón, 9°54' N, 84°16' W, 561 m, 10–13 vii 1990, T. W. Donnelly leg., en FSCA); *Argia elongata* n. sp. (Holotipo ♂, Costa Rica, Cártago Prov., Rio Reventazón, SE de Turrialba por autopista 10, 9°52'56" N, 83°38'49" W, 561 m, 10 viii 1979, R. W. & J. A. Garrison leg., en CSCA); *Argia haberri* n. sp. (Holotipo ♂, Costa Rica, San José Prov., Bosque del Tolomuco, km 118 en autopista Panamericana, en vegas y vertientes sobre una ladera con pasto y árboles, 9°28'18" N, 83°41'48" W, 1,710 m, 27 iii 2006, F. Sibley leg., en FSCA); *Argia schorri* n. sp. (Holotipo ♂, Costa Rica, Puntarenas Prov., 2.8 millas E de Golfito, 8°39' N, 83°7' W, 35 m, 4 vii 1967, O. S. Flint, Jr. & M. A. Ortiz B. leg., en USNM), y dos que hasta la fecha solo se conocen de México y Ecuador respectivamente: *Argia rudolphi* n. sp. (Holotipo ♂, México, Puebla State, Zihuateutla, Sierra de Huachinango, La Unión, en escurriadero, 20°14'25" N, 97°53'38" W, 596 m, 21 v 1987, R. Novelo & A. Gómez leg., en CSCA) y *Argia schneideri* n. sp. (Holotipo ♂, Ecuador, Napo Prov., Las Palmas, en Río Anzu en la Cuenca del Río Napo, 11 xii 1936, W. Clark-MacIntyre leg., en UMMZ). Todas las especies nuevas, así como las especies cercanamente emparentadas necesarias para diagnóstico incluyendo a *A. anceps* Garrison, *A. cupraurea* Calvert, *A. cuprea* (Hagen), *A. extra-*

nea (Hagen), *A. fissa* Selys, *A. fulgida* Navás, *A. oenea* Hagen in Selys, *A. popoluca* Calvert, *A. rhoarsi* Calvert, y *A. westfalli* Garrison son ilustradas y diagnosticadas de sus congéneres y su distribución conocida es mapeada.

Palabras clave: Libélulas, Neotrópico, nuevas especies, diagnosis, mapas de distribución

Introduction

Costa Rica constitutes a biodiversity hot-spot, with at least 270 species of odonates recorded from this small country of only 51,100 square kilometers (Esquivel 2006; Haber & Wagner 2013). Numerous endemisms and species from both North and South America that reach their distribution limits here are found within its diverse tropical rainforests, deciduous, cloud, and Mangrove forests. Although the odonate fauna of Costa Rica is better known than that of any other Central American country, several undescribed species collected in the past are still awaiting description, and there is a high likelihood of even more new species being discovered.

The genus *Argia*, found exclusively in the New World, is the most speciose genus of Odonata in the world. Approximately 200 names have been proposed or have been used in combination with this name since it was first established by Rambur (1842), and it currently includes 126 described species (Garrison & von Ellenrieder 2016). In Costa Rica, *Argia* is represented by 28 species, including the five new species described here as a continuation of our 2013 contribution (Garrison & von Ellenrieder 2013). For comparative purposes we also describe one new species of *Argia* from Mexico and one from Ecuador that resemble two of the new Costa Rican species.

Methodology

For this study we examined almost 2,000 specimens of *Argia*, including new species and related congeners. Specimens were first sorted to morphospecies based primarily on morphology of the caudal appendages and genital ligula of males and mesostigmal laminae of females. Other characters such as the number of postquadrangular cells and body color and patterning were also used in allocating specimens to taxa. The main morphological structures of diagnostic value in this genus and their terminology were described by Garrison (1994) in his study of the North American species, and the procedure to prepare them for examination and illustration was detailed by Garrison & von Ellenrieder (2015). Nomenclature follows Garrison *et al.* (2010). Abbreviations used throughout the text are as follows: Fw: forewing; Hw: hindwing; Pt: Pterostigma; PX: Postnodal crossvein; S1–10: abdominal segments 1 to 10; Dept.: Department; Dist.: District; Prov.: Province.

New species are treated alphabetically. Each species account includes type material information, list of specimens examined, description, diagnosis, remarks, habitat from which adults were collected, distribution, and illustrations of all diagnostic characters including variability when observed.

Illustrations were made with the aid of a camera lucida coupled to Nikon SMZ1500 and Zeiss SteREO discovery V20 stereomicroscopes. Multiple drawings are included to illustrate observed variability of characters. Macrophotographs of the head, thorax, and parts of the abdomen of dried specimens were edited with Adobe Photoshop to match colors from photographs of live specimens. Coloration depicted for these illustrations should be considered approximate and may not match field-collected material especially in terms of intensity of pale colors. All photographs were rendered from fully mature specimens; teneral and juvenile specimens normally possess lighter pale colors, and females of some species may be dichromatic (brown or blue) in their pale coloration. Photographs, scans, and illustrations are not to scale, and names on plates referring to new species are framed.

Measurements are given in millimeters; dimensions are given as average ± standard deviation followed by range in square brackets and were taken from ten specimens when available; hindwing measurement excludes basal sclerites; total length includes appendages and ovipositor (excluding styli), but abdomen length excludes them.

Maps were created electronically using Arc View 9.3. Longitude/latitude coordinates provided in the original labels are indicated in parentheses; approximate coordinates culled from Brown (1941) and Google Earth when not provided in the original labels are indicated in curly brackets.

The following acronyms for collections and collectors are used throughout the paper:

ACR	Andrew C. Rehn, Sacramento, California, USA
BMNH	British Museum of Natural History, London, UK
CAS	California Academy of Sciences, San Francisco, California, USA
CEH	Carlos Esquivel Heredia, Heredia, Costa Rica
CEUA	Universidad de Antioquia, Medellín, Antioquia, Colombia
CSCA	California State Collection of Arthropods, Sacramento, California, USA
DRP	Dennis R. Paulson, Seattle, Washington, USA
FSCA	Florida State Collection of Arthropods, Gainesville, Florida, USA
INBIO	Instituto Nacional de Biodiversidad, Heredia, Costa Rica
JJ	Jim Johnson, Vancouver, Washington, USA
JJD	Jerrell Daigle, Tallahassee, Florida, USA
KJT	Kenneth J. Tennessen, Wautoma, Wisconsin, USA
LJ	Laurent Juillerat, Neuchâtel, Switzerland
MIZA	Museo del Instituto de Zoología Agrícola, Maracay, Venezuela
MNHN	Muséum National d'Histoire Naturelle, Paris, France
RWG	Rosser W. Garrison, Sacramento, California, USA
TWD	Thomas W. Donnelly, Binghamton, New York, USA
UAC	Universidad de Los Andes, Bogotá, Colombia
UAM	University of Alabama Museums, Tuscaloosa, Alabama, USA
UMMZ	Museum of Zoology, University of Michigan, Ann Arbor, Michigan, USA
UNAM	Universidad Nacional Autónoma de México, Distrito Federal, Mexico
USNM	National Museum of Natural History, Smithsonian Institution, Washington D.C., USA
WAH	William A. Haber, Monteverde, Puntarenas, Costa Rica

Comparative specimens of other *Argia* species examined for diagnosis of the new species, including *A. anceps* Garrison, *A. cupraurea* Calvert, *A. cuprea* (Hagen), *A. extranea* (Hagen), *A. fissa* Selys, *A. fulgida* Navás, *A. oenea* Hagen in Selys, *A. popoluca* Calvert, *A. rhoadsi* Calvert, and *A. westfalli* Garrison, are listed in the Appendix.

To explore genetic differences between color morphs of *Argia fulgida* the 16S gene of mitochondrial DNA of several specimens of both color morphs was sequenced. GenBank accession numbers for sequenced specimens are provided in the Appendix.

Odonate sample DNA extraction, amplification and analysis: From legs of dried single adult specimens, gDNA was extracted using a modified non-destructive insect protocol for the DNEasy Blood and Tissue Kit (Qiagen Inc., Valencia, CA, Cat. No. 69506). Legs were placed in individual 1.5 ml microcentrifuge tubes (USA Scientific) with 20µl Proteinase K solution and 180µl ATL buffer and incubated for 24 hours in a 55° C water bath. 200 µl manufacturer's AL buffer was added to each tube and sample vortexed briefly and incubated at 70° C for ten minutes. 200 µl of 100% EtOH was added to each tube and vortexed briefly. The mixture was pipetted into DNEasy Spin Column and centrifuged at 8,000 g for 1 minute. Flow through was discarded and 500µl of buffer AW1 was added to the column and centrifuged at 8000g for 1 minute. Flow through was discarded, 500µl of buffer AW2 was added to the column. Column was centrifuged at 20000g for 3 minutes to dry the column. 100µl of buffer AE was pipetted onto column filter and allowed to rest for several minutes and then centrifuged at 8000g to elute. Polymerase Chain Reaction (PCR) was carried out in an Eppendorf Mastercycler thermal cycler. PCR was performed with the following conditions for each reaction: 0.5 U Platinum Taq (Invitrogen), 5µl of manufacturer's 10X buffer (20mM Tris -HCl pH8.4 and 500mM KCl), 2.5mM MgCl₂, 20µM dNTP's (Sigma), 0.1µM each primer —LR-J-12887 (5' CCGGTCTGAACTCAGATCACGT 3') and LR-N- 13398 (5' CGCCTGTTAACAAAAACAT 3') (Simon *et al.* 1994), and ddH₂O to 45µl. 5µl of DNA template was added to the reaction. Amplification was carried out for 35 cycles using annealing temperature at 55°C for 30 s and extension at 72°C for 1 min. The PCR products were purified to remove unincorporated primers and nucleotides using Qiagen QIAquick PCR Purification Kit following the manufacturer's protocol. Sanger sequencing reactions were performed by GeneWiz using the same forward and reverse primers. Electropherograms for the CO1 gene were edited and aligned with Sequencher, version 4.6 . Sequences were manually aligned with MacClade, version 4.08 and edited to 503 base

pairs for all taxa. Estimates of evolutionary divergence between sequences were calculated with MEGA5 (Tamura *et al.* 2011). The evolutionary history was inferred by using the Maximum Likelihood method based on the Jukes-Cantor model (Jukes & Cantor 1969). The percentage of replicate trees in which the associated taxa clustered together in the bootstrap test (400 replicates) are shown next to the branches (Felsenstein 1985) in the tree (Fig. 191). Branches corresponding to partitions reproduced in less than 50% bootstrap replicates are collapsed. Initial tree(s) for the heuristic search were obtained automatically as follows: when the number of common sites was < 100 or less than one fourth of the total number of sites, the maximum parsimony method was used; otherwise BIONJ method with MCL distance matrix was used. The analysis involved 9 nucleotide sequences. There were a total of 503 positions in the final dataset.

TABLE 1. Names used or associated with *Argia* species treated in this paper. Number in brackets ([n]) under Reference = reprint pagination for names proposed by Hagen & Selys (1865). Names in **bold italic** = new species. Names in *italic* are treated in diagnostic sections under various new species accounts.

New species descriptions

Argia calverti Garrison & von Ellenrieder, n. sp.

Figs. 1 (head ♂), 5 (labrum ♀), 13 (head, thorax, S1–4 ♂); 35 (head, thorax, S1–4 ♀); 56 (S7–10 ♂), 80 (S7–10 ♀), 106 (hind margin of prothorax ♀), 107 (mesostigmal plates ♀); 148 (appendages ♂); 165 (map); 172 (field picture of ♂); Table 2 (measurements).

Etymology. Named *calverti* (Latinized name) in honor of the late Philip Powell Calvert (1871–1961), in recognition to his valuable contributions to the knowledge of Central American Odonata culminating in his contribution to the Neuroptera volume of the *Biologia Centrali-Americana* (1901–1908).

Specimens examined. 35 ♂, 14 ♀. **Types.** Holotype ♂: COSTA RICA, Cartago Prov., Reserva Tapantí, 1,310 m, 6 vii 1963, F. G. Thompson leg. [FSCA]. Paratypes: COSTA RICA, Alajuela Prov.: 1 ♂, Peñas Blancas

River Valley, Monteverde Cloud Forest Reserve, Refugio Alemán, small tributary down trail from Refugio (10°18'28" N, 84°44'25" W, 1,037 m), 1 viii 2007, W. A. Haber & L. Ramirez leg. [RWG]; Cartago Prov.: 2 ♂, Río Chiriquí, just N of Peralta (9°58'49" N, 83°36'25" W, 348 m), 25 iii 1910, P. P. Calvert leg. [FSCA]; 2 ♂, 1 ♀, A.C. Amistad, Turrialba, Tayutic, Grano de Oro, Chirripo (9°49'6" N, 83°27'33" W, 1,120 m), 19–30 vi 1993, P. Campos leg. [INBIO]; 2 ♂, 1 ♀, Tapantí {9°43' N, 83°46' W}, 1,310 m, 6 vii 1963, F. G. Thompson leg. [FSCA]; 1 ♂, same data but [RWG]; Guanacaste Prov.: 1 ♂, 1 ♀ [in tandem], Guanacaste National Park, Estación Cacao, SE side of Volcán Cacao (10°55'53" N, 85°27'43" W, 1,299 m), 21–29 v 1992, M. A. Zumbado leg. [INBIO]; 1 ♂, 1 ♀ [in tandem], same data but Estación Biológica Maritza, trail to Cacao Station, river in secondary forest, perching on rocks near water in rapids (10°57'25" N, 85°29'42" W, 590 m), 31 viii 1990, M. A. Zumbado leg. [INBIO]; 1 ♂, 1 ♀ [in copula], same data but Quebrada Tempisquito (10°57' N, 85°30' W, 600 m), 25 viii 1990, G. Varela leg. [INBIO]; 1 ♂ same data but 29 viii 1990, M. A. Zumbado leg. [INBIO]; 1 ♂, 1 ♀ [in tandem], same data but 6 v 1991, J. Zloty leg. [RWG]; 1 ♂, 1 ♀, Río Góngora, on stones in the river and along river margins (10°52'44" N, 85°32'19" W, 600 m), 8 v 1989, CEH leg. [CEH]; Heredia Prov.: 2 ♂, 2 ♀ [in copula], La Selva Biological Station, 10 km SW of Horquetas (10°18' N, 84°3' W, 600 m), 24–26 iii 1995, TWD & A. Ramírez leg. [TWD]; 3 ♂, 1 ♀, La Selva altitudinal transect, 1,070 m, 11 iv 2001, R. Vargas leg. [CEH]; 1 ♂, 1 ♀, Sarapiquí, Magsasay (10°24'6" N, 84°3'18" W), 20 ix 1993, J. Benstead leg. [CEH]; Limón Prov., 1 ♂, 11 km SSW of Pocora, Finca Las Brisas, on main river channel among boulders and rocks, Río Parismina and tributaries (10°4'10" N, 83°37'58" W, 821 m), 31 i 2007, WAH, D. Wagner & M. Thomas leg. [RWG]; San José Prov., 1 ♂, 15 km WNW of San Isidro de El General, on large river below Yoga Ashram of Tamara Budowski, small tributary of Río División, Quebrada Grande (9°24'36" N, 83°49'53" W, 1,124 m), 2 v 2010, WAH leg. [RWG]; 1 ♂, 1 ♀, Braulio Carrillo National Park (10°9'44" N, 83°56'18" W, 472 m), 24 iv 1983, K. D. leg. [RWG]; 2 ♂, 1 ♀, Parque Nacional Braulio Carrillo, Quebrada Sanguijuela (10°9'36" N, 83°57'47" W, 800 m), 6 vii 1989, CEH leg. [CEH]; Puntarenas Prov.: 2 ♂, Finca Las Cruces, 4 mi S of San Vito de Java {8°46'11" N, 82°57'35" W, 1,220 m}, 21 ii 1975, DRP leg. [RWG]; 2 ♂, 1 ♀ [one pair in tandem], Monteverde, Río San Luis Arriba, Río San Luis, along river below waterfall (10°16'42" N, 84°47'3" W, 1,180 m), 7 viii 2013, L. Ramírez leg. [RWG]; 1 ♂, same data but 20 ix 2013 [RWG]; 1 ♂, 1 ♀ [in tandem], same data but [CSCA]. PANAMA, Chiriquí Prov.: 2 ♂, Potrerillos (8°39' N, 82°29' W, 664 m), 18 ii 1935, J. W. MacSwain leg. [UMMZ]; Veraguas Prov.: 1 ♂, near Santa Fe, Quebrada Alto de la Piedra (8°30'53" N, 81°7'19" W, 850 m), 18 vi 2011, A. Donnelly leg. [FSCA]; 1 ♂, 1 ♀ (in tandem) about 3 km NW of Alto de Piedra on N.P. Santa Fe Road, tributary to Río Maluba, branches 1 & 2 (8°31'32" N, 81°7'48" W, 610 m), 25 v 2016, W. Mauffray leg. [FSCA].

A large red-eyed species with a brilliant cupreous thoracic dorsum and with dorsum of S1–7 largely blue, similar to pattern observed in *Argia cupraurea* Calvert.

Description of male holotype. Head: Entire face with metallic cupreous-red reflections except for the following: narrow apical margin of labrum, anteclypeus, base of mandibles and genae dark orange, small postocular spots blue, small pale spot anterolateral to lateral ocellus (similar to Fig. 1); antennae black, rear of head including margin except for narrow pale border along eye margin.

Prothorax entirely metallic cupreous-red except for blue anterior lobe. Mesothorax with mesepisternum brilliant cupreous-red, mesepimeron and mesinfraepisternum metallic dark purple; metepisternum and metepimeron blue interrupted by dark stripe along metapleural suture (as in Figs. 13, 172). Wings slightly smoky with venation black; pterostigma trapezoidal, dark brown, surmounting 1.5 cell in left Fw, 1.0 cells in right Fw, 1 cell in left Hw wing, 1.5 cells in right Hw; postnodals Fw 18/18, Hw 15/16; postquadrangular cells Fw 5/5, Hw 4/5; RP₂ at Fw 8/8, Hw 7/7. Coxae and trochanters brown anteriorly becoming blue posteriorly; femora, tarsi and armature black, tibiae black, pale externally.

Abdomen (as in Figs. 13, 56, 172) mostly blue; S1 black at basal 0.40 with ventrolateral extension laterally, remainder blue; S2 blue dorsally, laterally with a black stripe with pointed extension almost meeting dorsally at apical 0.20, below with a complete narrow, largely parallel blue stripe followed by black along ventral margin of tergite, annulus black; S3 blue with a narrow black stripe ventrally with a dorsal pointed extension at apical 0.05 but not meeting above, annulus black; S4–6 similar to S3 but posterior portion of black stripe more extensive; S7 blue with narrow ventral black stripe joining black annulus apically (as in Fig. 56); S8–10, blue dorsally with black stripe laterally, on S10 this stripe extending dorsally along posterior margin; torus pale, appendages black.

Genital ligula as in *Argia cuprea* (Figs. 126, 127), with a pair of small laterally extended lobes at base near flexure (these hidden by membranous terminal fold) followed by a pair of flexible chitinized branches, each arising

from a narrow stem at distal segment base extending laterad of the ligula; distal portion with narrow digit-like hood slightly inflated distally and extending over coiled digit-like paired flagella, the latter fused along a common stem basally and arching entally toward first segment.

Torus small, transversely oval, occupying entire ventral margin of torifer and not overlapping bilobed epiproct (Fig. 148c); base of epiproct and area around base black, apical portion of epiproct pale; cercus (Fig. 148) robust, longer than wide, about subequal to paraproct, strongly convex dorsally, branched apically with distal margin of shorter outer branch ending at approximate right angle to longer decumbent inner branch; medial margin strongly convex; cercus ventrally strongly concave with a basal lobe externobasally (Fig. 148d); paraproct bilobed, its ventral branch narrow, bluntly pointed, its base at about 120° from acutely pointed anteriorly directed dorsal branch.

Dimensions. Hw 26.4, abdomen 33.8, total length 44.1.

Description of female paratype (Costa Rica: Puntarenas Prov., Monteverde, Río San Luis Arriba, Río San Luis, along river below cataract; ♀ H 9123–4 in tandem with male). Head (Fig. 35): labrum with distal half ochre (as in Fig. 5), basal half metallic cupreous-red; anteclypeus ochre; postclypeus metallic cupreous; antefrons, genae and base of mandibles pale ochre; postfrons and remainder of epicranium metallic cupreous with pair of small spots anterolateral to lateral ocelli and small postocular spots pale bluish green; rear of head including margin except for narrow pale border along eye margin.

Prothorax metallic cupreous, anterior lobe pale blue, lateral 0.20 of posterior margin of hind lobe and propleuron pale ochre; pterothoracic dorsum (Fig. 35) black with cupreous reflections and with a pale ochre antehumeral stripe widening slightly ventrally; entire metepimeron metallic cupreous, divided at upper 0.20 with branches enclosing an irregular elongate pale ochre spot, mesinfraepisternum with anterior half black, remainder ochre; metathorax ochre except for narrow black stripe at metapleural suture; venter of thorax ochre; S1 pale olive with basal ring of black and with narrow posterior black ring; S2 largely black with cupreous metallic reflections with narrow pale middorsal line abruptly widening at apical 0.20 and followed below by a narrower pale longitudinal stripe laterally and bordered ventrally with black, annulus black; S3–7 similar but with a pale basal ring not connected above and with a further narrowing of pale middorsal and lateral stripes (similar to Fig. 87); S8 like S7 but with dorsal black expanding laterally and enclosing a pale middorsal spot at apical 0.20 and with additional pale stripe ventrally, posterior portion of sternum pale; S9 similar to S8 but with dorsal black divided middorsally forming a pair of lobes ending at apical 0.40 and with pale blue area connecting with pale lateral stripe, S10 largely black with pale blue spot dorsally; cerci black, ovipositor pale except for black ventral margin (Fig. 80).

Mesostigmal lobe (Fig. 107b) forming a small stubby upright lobe occupying medial 0.40 of slightly raised plate, medial margin of lobe well separated from branching middorsal carina by a low carina extending from medial base of lobe, medial margin of lobe strongly recurved in posterior view (Fig. 107e); mesostigmal lobe accompanied by a slight mesepisternal tubercle postero-distal to outer margin of erect lobe (Fig. 107c).

Variation in paratypes. On one male the pale postocular spot is absent on the right side and present as a small spot on the left side (Fig. 1). The holotype male is more heavily marked with black than majority of other specimens; S2 on most males has a lateral blue stripe extending full length (similar to Fig. 15) and in some, posteriorly connecting with dorsal blue; in others, there is a greater lateral extension of dorsal blue on S10. Females show little variation but some have the majority of S10 blue and the degree of metallic coloration on the thorax is tempered by age; older females tend to be less metallic. One female (Estación Cacao) has a greatly reduced dark humeral stripe similar to Fig. 34. Pterostigma surmounting 1–2 cells in males and females; postnodals: Fw 14–19, Hw 14–16 in males, Fw 15–19, Hw 13–17 in females; postquadrangular cells Fw 5, Hw 4–5 in males, Fw 4–6, Hw 4–5 in females; RP₂ at Fw 7–9, Hw 6–8 in males, Fw 7–8, Hw 6–7 in females. **Dimensions.** ♂: Hw 25.8 ± 1.52 [23.8–27.6], abdomen 33.8 ± 1.71 [31.2–36.1], total length 43.9 ± 2.27 [40.8–47]. ♀: Hw 26.4 ± 1.32 [23.5–28.2], abdomen 31.4 ± 1.77 [29–34], total length 41.3 ± 2.15 [38.2–44.5].

Diagnosis. Male belongs to a distinctive group of species possessing an entirely metallic cupreous thoracic dorsum and, in life, dorsal half of compound eyes red, although postmortem preservation may preclude the practical use of the latter as a diagnostic character. Within its range (Costa Rica, Panama, Fig. 165) male can be distinguished from similar metallic red species with largely blue S2–6 (*A. cupraurea*, *A. oenea*) by large size (Hw 23.8–27.2 mm; total length 40.8–47.0 mm; N = 10) compared to *A. cupraurea* (Hw 20.2–22.5 mm; total length 36.1–40.0 mm; N = 10) and *A. oenea* (Hw 18.5–22.6 mm; total length 33.8–39.7 mm; N = 10) and by the robust

and strongly curved cercus (Fig. 148a) versus the almost linear (Fig. 149a) and slightly arched (Fig. 150a) cercus in *A. cupraurea* and *A. oenea* respectively. The paraproct of *A. oenea* in lateral view (Fig. 150b) is almost linear with both branches small and of about the same size, almost bilobate; the dorsal or ventral branches of the paraproct of *A. calverti* (Fig. 148b) and *A. cupraurea* (Fig. 149b) are more robust and are strongly divergent. The labrum in *A. oenea* is largely pale (Fig. 3) but mostly metallic in *A. calverti* (Fig. 1) and *A. cupraurea* (as in Fig. 2). The hood of the genital ligula in *A. oenea* (Fig. 131) is quadrate, not linear and digit-like as in *A. calverti* and *A. cupraurea* (as in Figs. 126, 127).

A *cuprea*-like dark morph of *Argia fulgida* known from Costa Rica, western Panama, and Ecuador (Fig. 165) occurs within the range of *A. calverti*. Male of this color morph is unique among metallic species within the distribution range of *A. calverti* in having dorsum of S2–6 entirely black except for a narrow basal blue ring (Fig. 10); in the three other sympatric metallic species, *A. calverti* (Fig. 13), *A. cupraurea* (Fig. 14), and *A. oenea* (Figs. 15–16), the dorsum of S2–6 has at least basal half or more blue (Figs. 13–15) or violet (Fig. 16). S8 in *A. fulgida* is blue with the posterior half to third black (Fig. 54), differing from the entirely blue S8 in *A. calverti* (Fig. 56), *A. cupraurea* (Figs. 57–59) and *A. oenea* (Figs. 61–62). The broad explanate hood of the apical segment of the genital ligula in *A. fulgida* (Figs. 128–130) is shared with that of *A. oenea* (Fig. 131), and both differ from the largely long linear hood present in *A. calverti* and *A. cupraurea* (as in Figs. 126–127). The genital ligula of *A. fulgida* and *A. oenea* are similar in possessing a broad campanulate (*A. fulgida*, Figs. 128–130) to quadrate (*A. oenea*, Figs. 131b, c) hood but differ as follows: in *A. fulgida* the thickened flagella are not fused at base and they do not arch entally toward first segment (Fig. 128c); in *A. oenea*, the bifurcate flagella are fused into a common stem that arches entally toward first segment (Figs. 131a, c).

The male appendage, genital ligula, and female mesostigmal plate morphology of dark and pale S2–6 morphs of *A. fulgida* are essentially the same. *Argia fulgida* was described from a single male from Muzo, Colombia, which belongs to the pale morph with dorsum of S2–6 with at least the basal half or more blue (Figs. 11–12). Its appendages and genital ligula are illustrated here for comparative purposes (Figs. 129, 147). We have seen only one other specimen representing the pale morph from Colombia (Valle del Cauca Dept., San Jose, Río Dagua), but pale morphs of *A. fulgida* occur on the western side of the Andes of Ecuador (Bolívar, Los Ríos, Manabí, Pichincha, Santo Domingo de los Tsáchilas Provinces, Fig. 165). William Haber and Fred Morrison collected a pair of *A. fulgida* at a shallow forest stream in Ecuador (Pichincha Prov., road from highway to Silanche Bird Sanctuary, 10 km NW of Pedro Maldonado) whose male has a largely dark S2–6 as figured for Central American *A. fulgida* (Fig. 10). Additionally, a molecular analysis comparing mt DNA 16S sequences from one Costa Rican, two Panamanian, and four Ecuadorean specimens of *Argia fulgida* (including the Pichincha pair) shows that specimens displaying the two color morphs do not segregate into two groups based on this ribosomal gene (Table 5, Fig. 191), which was used to separate *Argia* species and to measure genetic divergence in previous studies (Caesar & Wenzel 2009; Nava Bolaños *et al.* 2016). All sequenced dark specimens from Panama are identical to several pale specimens from Ecuador, and the other sequenced specimens differ from them by 2 to up to 6% of the about 500 mtDNA 16S base pairs sequenced. At the present time we have found no evidence—morphological or molecular—that justifies treating these two color morphs as separate species, although future studies involving other genetic markers might prove otherwise.

Female of *A. calverti* can be easily distinguished from other similar species by the short, stubby mesostigmal lobe (Fig. 107) compared to the longer more foliate lobe in *A. fulgida* (Fig. 103), *A. cuprea* (Figs. 104, 105), *A. cupraurea* (Fig. 108), and *A. oenea* (Figs. 109, 110). Thoracic and abdominal coloration for females of all five species are similar (Figs. 30–38, 80–85).

Males of *A. calverti* and *A. fulgida* are two of the five species from North and Central America possessing an entirely metallic cupreous thoracic dorsum. In both of them a pair of chitinized branches arises from a narrow stem at the base genital ligula distal segment. Each branch arches dorsally (ectally), and becomes broader at tip where its outer margin is armed with an irregular series of small spines. These branches, which are best seen in dorsal (ectal) view, are flexible and extend laterally to dorsolaterally depending on preservation (Figs. 128–130). We have not found the armature of these structures to be species specific. Females also have a degree of metallic thoracic coloration, but this is confined to the medial half of the mesepisternum. In addition to their metallic thoracic coloration, they can usually be identified also by the presence of a pair of tuberculate processes or swellings each mediolaterally along the hind lobe of the prothorax, which gives a trilobate appearance to the hind margin (Fig. 106), although this condition may not be so pronounced in some females.

The keys below should allow for the identification of both sexes of these five species, although examination of the male genital ligula and details of the mesostigmal plates and associated mesepisternal tubercles coupled with overall body pattern may be necessary to confirm some identifications.

Key to Males

1. Dorsum of S2–6 entirely black except for a narrow basal blue ring (Figs. 9, 10; 176) 2
- 1'. Dorsum of S2–6 with at least the basal half or more blue (Figs. 13–15; 172–175) or violet (Fig. 16) 3
- 2(1) Dorsal membranous hood of genital ligula distal segment broadly campanulate basally, covering base of flagella (Figs. 128–130); outer branch of cercus in dorsal view small, quadrate and forming a right angle with the longer inner branch (Figs. 146a, c; 147a, c); Costa Rica, Panama, Colombia, and Ecuador (Fig. 165) *fulgida*
- 2' Dorsal membranous hood of genital ligula distal segment linear, forming a digit-like process (Figs. 126, 127); outer branch of cercus in dorsal view slightly acute and forming an acute angle with the larger inner branch (Figs. 145a, c); Sonora State in Mexico and Texas in USA south through Honduras (Fig. 166) *cuprea*
- 3 (1'). Labrum pale except for dark medial spot (Fig. 3); paraproct linear, with both branches small and of about the same size, almost bilobate (Fig. 150b); hood of genital ligula quadrate or nearly so (Figs. 131b, c); S Arizona and Texas in USA, Baja California in Mexico, south through central Panama (Fig. 166) *oenea*
- 3' Basal half or more of labrum dark metallic (Figs. 1, 2, 5); paraproct with dorsal and ventral branches unequal in size, strongly divergent (Figs. 148a, b, 149a, b); hood of genital ligula linear, digitiform (as in Figs. 126, 127); Guatemala south through Panama and east through Venezuela (Figs. 165, 166) 4
- 4(3') Medial margin of cercus in mediadorsal view strongly arched, with apical portion recurved ventrally at about 90° (Fig. 148a); larger species (Hw 23.8–27.6 mm; total length 40.8–47.0 mm) Costa Rica and Panama (Fig. 165) *calverti*
- 4(3') Medial margin of cercus in mediadorsal view approximately linear (Fig. 149a); smaller species (Hw 20.2–22.5 mm; total length 36.1–40.0 mm); Guatemala south through Colombia and east to Venezuela (Fig. 166) *cupraurea*

Key to Females

Note: The following key should work for most females by comparison of all characters and with reference to descriptions and diagnoses under *A. calverti* and *A. fulgida*. However, we have observed variability in morphology of the mesostigmal plates and associated structures as well as color pattern. Interspecific tandems (e.g. male *A. oenea* with female *A. cupraurea*) have also been observed, which may further make specific identifications difficult.

1. Mesostigmal lobes small, occupying medial half or less of posterior margin of plate (Fig. 107), larger species (Hw 23.5–28.2 mm; total length 38.2–44.5 mm); Costa Rica and Panama (Fig. 165) *calverti*
1. Mesostigmal lobes large, foliate, occupying medial half or more of posterior margin of plate (Figs. 103, 104, 108–110), smaller species (Hw 18.5–25.4 mm, Total length 32.8–42.0 mm); Arizona and Texas in USA south through Panama (Fig. 166) 2
- 2(1'). Labrum without metallic coloration (Fig. 4) or with a medial basal spot (Fig. 8), dark humeral thoracic stripe usually forked at basal 0.50 or more (Fig. 37), S3–5 with relatively broad spindle-shaped pale mark dorsally (Fig. 88); Arizona and southern Texas in USA south through Panama (Fig. 166) *oenea*
- 2'. Labrum with metallic coloring at least on its basal half (except for some *A. cupraurea*) (Figs. 5–7), dark humeral thoracic stripe usually forked at upper 0.40 or more (Figs. 30–32, 35, 36), S3–5 with thin pale middorsal line only (Fig. 87); southern Texas in USA south through Panama (Fig. 166) 3
- 3(2'). Space between tips of mesostigmal lobes in dorsal view narrow, about one to one-and-a-half times as wide as width of each lobe at base (Figs. 108a, c); mesostigmal lobe elongate, longer than wide, parallel sided, erect, its tip unmodified (Fig. 108b), extending for more than three times the height of the vestigial mesepisternal tubercle when viewed in oblique lateral view (Fig. 108f); Guatemala south through Colombia and east to Venezuela (Fig. 166) *cupraurea*
- 3'. Space between tips of mesostigmal lobes in dorsal view wider, but less than twice as wide as width of each lobe at base (Figs. 103a, c; 104a, c; 109a, c); mesostigmal lobe roundly quadrate, its upper portion thickened, or slightly depressed, or slightly bent posteriorly, its tip extending for less than twice the height of the mesepisternal tubercle when viewed in oblique lateral view (Fig. 103f). 4
- 4 (3'). Mesostigmal lobe with medial margin recurved (visible in posterior view, Fig. 103e); southern Texas in USA south through Honduras (Fig. 166) *cuprea*
- 4'. Mesostigmal lobe with medial margin unmodified (visible in posterior view, Fig. 104e, 105e); Costa Rica, Panama, Colombia, and Ecuador (Fig. 165) *fulgida*

Habitat. According to W. Haber (pers. comm.), adults perch on rocks and boulders near rapids and along margins in rivers and streams, within primary and secondary forest. Specimens were taken at elevations ranging from about 470 m (Costa Rica: Braulio Carrillo National Park) to over 1,300 m (Costa Rica: Tapantí). Flight dates range from January (11 km SSW of Pocora) through September (Monteverde).

Distribution. Costa Rica and Panama (Fig. 165). It occurs in sympatry with other metallic congeners, including *A. cupraurea*, *A. fulgida*, and *A. oenea* (Figs. 165, 166).

TABLE 2. Wing counts and measurements (average and standard deviation followed by range in square brackets) for metallic *Argia* species treated in this study.

***Argia carolus* Garrison & von Ellenrieder, n. sp.**

Figs. 24 (head, thorax, S1–4 ♂); 47–49 (head, thorax, S1–4 ♀); 73 (S7–10 ♂); 96–98 (S7–10 ♀); 119 (mesostigmal plates ♀); 138 (genital ligula); 158 (appendages ♂); 169 (map); 184 (field picture of ♂); 185 (field picture of ♀); Table 4 (measurements).

Etymology. Named *carolus* (to be treated as an indeclinable noun) in honor of our friend and colleague Carlos 'Carolus' Esquivel Heredia, in recognition to his valuable contributions to the knowledge of Costa Rican odonates and his kind help and camaraderie during our studies in that country.

Specimens examined. 49 ♂, 7 ♀. **Types.** Holotype ♂: COSTA RICA, San José Prov.: Reserva Biológica El Rodeo, 7 km W of Villa Colón ($9^{\circ}54' N$, $84^{\circ}16' W$, 795 m), 10–13 vii 1990, TWD leg. [FSCA]. Paratypes: COSTA RICA, Puntarenas Prov.: 1 ♂, La Guaría, 8 km SSW of Santa Elena on road to Interamerican highway, Quebrada Guaría, small side flood channel ($10^{\circ}14'55'' N$, $84^{\circ}50'52'' W$, 597 m), 4 viii 2006, WAH & E. Cruz leg. [RWG]; 1 ♂, Río Cataratas at Pan-American highway ($9^{\circ}5'29'' N$, $83^{\circ}16'14'' W$, 160 m), 8 iii 2009, F. C. Sibley leg. [RWG]; 1 ♂, Golfito, Gamba ($8^{\circ}42'11'' N$, $83^{\circ}11'15'' W$, 80 m), ii 2007, S. Schneeweih & F. Hofhansl leg. [CEH]; 2 ♂, forest interior W of Gamba ($8^{\circ}42'7'' N$, $83^{\circ}10'47'' W$, 200 m), xii 2015, S. Degenhart leg. [RWG]; 1 ♀, same data but ($8^{\circ}41'2'' N$, $83^{\circ}10'51'' W$, 130 m), i 2016, S. Degenhart leg. A medium-sized largely dark species with forcipate male appendages (Fig. 158).

Description of male holotype. Head: entirely black with following parts pale (purple): labrum, base of mandibles, genae, anteclypeus, postfrons, postocular spots and small pale spot anterolateral to lateral ocellus; antennae black, rear of head black except for pale narrow margin bordering eye margin (similar to Fig 24).

Prothorax black with following areas pale: anterior lobe, dorsolateral spot on middle lobe, lateral 0.30 of posterior margin of propleuron. Pale areas of pterothorax purple, with broad black middorsal stripe about four times as wide as pale antehumeral stripe, the latter gradually narrowing dorsally to about 0.50 width of base; black humeral stripe extending from anterior 0.80 base of mesinfraepisternum and narrowing above to about 0.50 of basal width, slightly emarginate posteriorly at mesopleural fossa and connecting narrowly below antealar crest with middorsal stripe above and with a short ventrally directed finger on dorsal portion of obsolete interpleural suture; metapleural suture with a narrow elongate black spot at metapleural fossa; posterior carina of metepimeron narrowly rimmed with black; pale colors on side of thorax purple. Wings hyaline with venation black; pterostigma dark brown, surmounting 1.5 cells in all wings; postnodals Fw 17/17, Hw 15/15; postquadrangular cells Fw 4/4, Hw 4/4; RP₂ at Fw 8/8, Hw 7/7. Coxae and trochanters black with a wash of brown medially; femora, tibiae, tarsi and armature black.

Abdomen (as in Figs. 24; 73; 184) mostly black; S1 with a black basal ring, remainder purple; S2 black with an incomplete pale (purple) dorsal campanulate spot occupying basal 0.60 of segment, laterally black with an indistinct pale lateral stripe; S3 black except for narrow basal ring extended dorsally into a point ending at basal 0.20 of segment; S4 similar to S3 but with only a narrow pale basal ring; S5 with an obscure pale lateral spot basally; S6–8 entirely black; S9–10 blue dorsolaterally and ventrally black; S10 black; torus pale, appendages black.

Genital ligula (Fig. 138), ending in a pair of flexible curved distal flagella strongly arching basally before uniting in a common stem that is partly covered by a broad, quadrate ectal hood (Fig. 138a); ental surface of genital ligula distal to flexure smooth (Fig. 138c); latero-basal portion of apical segment with an acute sclerotized lobe laterally, its tip ending just before flexure; inner fold present, sclerotized portion proximal to flexure lacking a microspinulate patch on ental surface on each side.

Torus narrow, transversely oval, swollen ventrally, occupying ventral half of torifer and not overlapping bilobed epiproct (Fig. 158c); area around epiproct black; epiproct black except for small pale medial lobe and margin of lateral lobes; cercus (Figs. 158a, c) about three times longer than wide, narrowing distally abruptly at distal third, extending beyond paraproct, divided apically into a small bluntly triangular lobe and meeting longer linear branch at about a right angle; inner branch long forming slightly inflated capitate glabrous tooth; medial margin slightly concave apically, convex basally, planate dorsomedially; paraproct (Fig. 158b) bilobed, its ventral branch subequal to upper branch, ventral branch triangular, its tip acute; upper branch a rounded lobe.

Dimensions. Hw 23.7, abdomen 31.2, total length 39.7.

Description of female paratype (Costa Rica: San José Prov., 4 km S of Tinamaste, Río Diamantes). Head, pro-, pterothorax and S1–2 as in male (Fig. 49) but pale colors orange brown; black humeral stripe more deeply divided at distal 0.30, the anterior (main) fork narrow and enlarged at mesopleural sulcus; pale dorsal campanulate spot smaller than in holotype; S3 with incomplete narrow pale basal ring; S4–7 entirely black; S8 black with blue distal spot occupying apical 0.50 with narrowing offshoot extending anteriorly to basal 0.30; S9 black with posterior 0.50 blue extending laterally and projecting anteriorly to basal 0.30; S10 blue dorsally, black ventrally, cerci and ovipositor black (Fig. 98).

Mesostigmal lobe as in Fig. 119, well developed but small, forming a flat, medially directed digit-like lobe elevated above depressed area on mesepisternum and not overlying branch of middorsal carina; base of lobe in dorsal (as in Figs. 119c, d) and anterior (as in Figs. 119a, b) views slightly swollen anteriorly, accompanied by a weak transverse carina; distal base of lobe slightly angulate posteriorly, thus setting off lobe from rest of mesostigmal plate; in posterior view (as in Fig. 119e) lobe thickened externally but lacking a tubercle at juncture with mesepisternum; a small mesepisternal tubercle present at latero-basal margin of mesostigmal lobe.

Variation in paratypes. Variation exists in extent of thoracic and abdominal markings as well as pale color. Fully adult male in life is a dark olive purple which turns almost black in preserved material, even if properly acetoned. Fully adult male often dusted with white pruinosity on sides of thorax especially on metathorax; black humeral stripe in most males as in Fig. 24 but in one male (Hacienda El Rodeo), the stripe is not forked, and it gradually narrows above to about the thickness of the metapleural stripe; another male (Hacienda El Rodeo) similar to that in Fig. 47. In contrast to male, female varies in pale thoracic coloration from orange brown (Figs. 47, 49) to dark olive green (Fig. 48) to purplish (Fig. 185) as well as development of black humeral stripe. Pale spots on S8–10 vary in size and reduction as shown in Figs. 96, 97. Some females lack a carina at anterior base of mesostigmal lobe but distal base of lobe slightly angulate posteriorly thus setting of lobe from rest of mesostigmal plate. Pterostigma surmounting 1–2 cell in males, 1–1.5 in females; postnodals: Fw 14–17, Hw 13–15 in males, Fw 14–16, Hw 12–14 in females; postquadrangular cells Fw 4, Hw 3–4 in males and females; RP₂ at Fw 7–8, Hw 6–7 in males and females. **Dimensions.** ♂: Hw 22.2 ± 1.11 [20.8–23.9], abdomen 29.8 ± 1.43 [27.6–32.1], total length 38.5 ± 1.8 [35.8–41.5]. ♀: Hw 21.8 ± 2.3 [18.5–24.7], abdomen 26.5 ± 2.3 [23.3–29.3], total length 34.9 ± 3.3 [30.5–38.5].

Diagnosis. Male unique by elongate forcipate shape of cercus (Fig. 158a). No other species within its range is similar. *Argia schneideri* (Fig. 159) also has a forcipate cercus but it is longer, extends beyond the level of the paraproct and it lacks the accessory lobe along the distal margin at the distal fourth of the appendage. The genital ligula of *A. schneideri* (Fig. 139) consists of a long single flagellum instead of the pair present in *A. carolus* (Fig. 138), and the former species also lacks the large quadrate hood and aciculate recurved lateral lobes present in *A. carolus*. In the female, the small, mesally directed mesostigmal lobe accompanied by a swollen base and slightly angulate external base is distinctive. The lobe is similar to that of *A. schneideri* (Fig. 120) but is considerably smaller, about two-thirds the size of that of *A. carolus*. In both sexes of *A. schneideri*, the black humeral stripe is not forked or encompasses a small pale isolated spot just below the alar carina (Figs. 25, 50); in *A. carolus*, a forked humeral stripe of varying height and condition is usually present (Figs. 24, 47–49).

Habitat. We collected a few specimens of this dark species at a small, partially shaded, moderately flowing

rocky stream at Hacienda El Rodeo on 28 May 2013. Part of the stream was exposed due to clearing of vegetation. *Argia carolus* was collected at the stream where it entered the shady undisturbed forest. Adults were inconspicuous due to their overall dark color. Other species collected here included *Argia anceps*, *A. cupraurea* (one female in tandem with a male of *A. oenea*), *A. frequentula* Calvert, *A. oculata* Hagen in Selys, *A. oenea* and *A. rogersi* Calvert. Haber and Sibley describe the Río Diamantes as a "stream with small and large rocks, about 5 m across". They noted the following for the female: "Tandem at 11:01 with 5909 [male]. Flew up from riffle area with collected mats of dead vegetable debris; apparently ovipositing." At the Río Cataratas, Sibley found this species to be "Fairly common along fast flowing, rocky stream through forest." Specimens were taken at elevations ranging from about 20 m (Parque Nacional Corcovado) to about 1,600 m (Estación de Biología Tropical Río Macho). Flight dates range from March (Río Diamantes) through September (Estación de Biología Tropical Río Macho).

Distribution. *Argia carolus* seems to be endemic to the Pacific slope of Costa Rica. Its most similar congener, *A. schneideri*, is clearly allopatric, being restricted as far as known to Ecuador (Fig. 169). We suspect that *A. carolus* will eventually be found in neighboring Panama.

Argia elongata Garrison & von Ellenrieder, n. sp.

A common medium-sized vivid blue species similar in appearance to the more northerly *Argia extranea* (Hagen).

Description of male holotype. Head (Fig. 17): Labrum, ante- and postclypeus, ante- and postfrons, base of mandibles and genae blue; base of postfrons with black inverted T connecting to black on epicranium, the latter interrupted by large blue postocular spots each broadly confluent with compound eyes, blue occipital bar interrupted forming three spots, two lateral, the third one a small crossbar medially, a small triangular blue spot anterolateral to lateral ocellus and a small longitudinal blue spot between lateral ocelli; antennae black; rear of head pale except for wash of brown on each side of occipital foramen.

Prothorax black with following areas blue: anterior lobe, dorsolateral spot on middle lobe, narrow elongate diagonal spot on lateral portion of propleuron with posterior margin rimmed in black. Pale areas of pterothorax vivid blue, with black middorsal stripe slightly narrowed at basal 0.20, about as wide as blue antehumeral stripe; anterior half of mesinfraepisternum black, continuous with broad humeral stripe at base then abruptly narrowing at basal fifth along mesopleural suture then abruptly forming a thin hairline at 0.50 before expanding again at mesopleural fossa; remainder of thorax blue except for narrow black stripe on metapleural suture (Fig. 17). Wings hyaline with venation black; pterostigma dark brown, surmounting 1 cell in all wings; postnodals Fw 15/16, Hw 15/14; postquadrangular cells Fw 4/4, Hw 3/3; RP₂ at Fw 7/7, Hw 5/5.5. Coxae and trochanters pale except for

black on dorsum of trochanters; femora black, interior surface pale; tibiae black with extensor surface pale, tarsi and armature black.

Abdomen (Figs. 17, 63) mostly blue; S1 blue with a narrow irregular black ring basally; S2 blue with an irregular black lateral stripe ending at apical 0.25, its anterior end connecting as a narrow black ring above, its posterior end sending a narrow triangular offshoot dorsally but connecting above, annulus black; S3 blue, ventrally with broad black stripe beginning at basal 0.10 and interrupted at dorsal margin at distal 0.60 by a narrow elongate blue spot, lateral black stripe extending dorsally at apical 0.20 and connecting dorsally isolating small blue middorsal and lateral spots posteriorly before black annulus; S6–7 similar but blue with no isolated posterior middorsal blue spot; S7 with broad black lateral stripe not interrupted medially; S8–9 blue with incomplete lateral black stripe below, posterior margin of S10 rimmed in black up to torus and with a complete narrow black middorsal stripe connecting basally with a narrow black ring; torus pale, its ventral margin rimmed with black; cercus brown; paraproct blue dorsobasally, remainder black.

Genital ligula (as in Fig. 132) ending in a triangular apical lobe, laterally with a small posteriorly directed lobe at basal 0.50 (as in Fig. 132b); apical portion of genital ligula slightly concave entally (as in Fig. 132c) and lacking any accessory structures; lateral sclerotized portion proximal to flexure lacking a microspinulate patch on ental surface on each side.

Torus large, swollen, transversely oval, occupying entire ventral margin of torifer but not overlapping bilobed epiproct (Fig. 151a); epiproct pale, black laterally; cercus quadrate in dorsal view with outer margin about twice the length of inner margin (Fig. 151c); in mediadorsal view dorsal surface slightly concave with a broadly based distal tooth at basal 0.50 (Figs. 151a, d); in lateral view narrowly triangular, about half length of paraproct (Fig. 151b); paraproct deeply forked, dorsal branch forming a broadly based triangle; ventral branch narrow, digitiform, meeting dorsal branch at a right angle, about 1.5 times as long as dorsal branch, its tip slightly curved mesad (Fig. 151a).

Dimensions. Hw 22.7, abdomen 28.6, total length 37.2.

Description of female paratype (Honduras: Cortés Dept.: Santo Tomás Camp, river behind camp, muddy, on low vegetation, Cusuco National Park, Figs. 39, 40, 89). Similar to male but pale colors light olive tan. Head, pro-, pterothorax as in male but with pale color on S1–2 more extensive; legs largely tan with streaks of brown on outer surfaces of femora and inner portion of tibiae at distal 0.40; S1–2 similar to male but pale coloration more extensive; S3–6 pale with a complete narrow ventral stripe and above an isolated elongate postbasal streak followed by a shorter apical spot that dorsally connects above; these stripes becoming more extensive on succeeding segments with postbasal and apical lateral spots connecting with ventral stripe; S7 (Fig. 89) mostly black except for narrow pale basal ring and vestiges of a pale lateral stripe; S8–10 pale except for small apical spot laterally on each segment; cerci black; ovipositor pale, sternite 8 and ovipositor pale rimmed with black dorsally and ventrally.

Mesostigmal lobe forming a low evenly raised lobe continuous with distal margin of plate; in anterior view, lobe forming an elongate raised lobe (Figs. 111a, b); an elongate raised tubercle posterior to plate at junction with mesepimeron when viewed posteriorly (Fig. 111e) an elongate depressed area paralleling medial portion of mesostigmal lobe on anterior portion of mesepisternum when viewed dorsally (Figs. 111c, d).

Variation in paratypes. Both sexes vary as to extent of dark markings on thorax and especially abdomen. The humeral stripe in both sexes is usually as depicted in Fig. 17 but in rare instances the humeral stripe is forked above (as in Fig. 22) in males (Chiapas State, canyon below Ixhuatan, 2.7 SW of Unión Juarez) or the posterior fork is present but isolated (as in Fig. 21; El Salvador: Santa Ana Dept., El Limo Ranch); five other males (Panama: Cero Azul; Finca Hartmann; Bambito, Mata Ahogado; El Valle de Antón) have the upper hairline portion of the humeral stripe thickened (as in Fig. 21), but all of these conditions are rare. Extent of black markings on S7–10 is variable, ranging from a thin linear stripe on basal 0.70 of S7 (Fig. 66) to a more normal broad stripe (Figs. 63–65); ventral black on S8–9 may occasionally be absent (Figs. 65, 66). Pterostigma surmounting 1–2 cells in males, 1–1.5 in females; postnodals: Fw 12–17, Hw 10–15 in males, Fw 13–18, Hw 11–15 in females; postquadrangular cells Fw 3–4, Hw 3 in males, Fw 4, Hw 2–3 in females; RP₂ at Fw 6–8, Hw 5–7 in males and females. **Dimensions.** ♂: Hw 21.9 ± 1.53 [18.8–23.4], abdomen 28.5 ± 1.71 [24.5–30.4], total length 36.6 ± 1.89 [32.2–38.6]. ♀: Hw 22.7 ± 1.7 [20–23.9], abdomen 26.3 ± 1.42 [23.7–29.1], total length 34.2 ± 1.81 [31.2–37.8].

Diagnosis. This species closely approaches the more northerly *A. extranea* in color pattern (Figs. 177–180) and morphology. Both sexes may be separated by the following key:

1. Males 2
- 1'. Females 3
- 2(1). Distal segment of genital ligula with a small digitiform appendage on its ental tip (Figs. 133a, c); cercus in medioposterior view with decumbent tooth at approximately basal 0.30 of margin (Figs. 152d, e–g), and with distal margin often produced into a tubercle, this area immediately preceded by a shallow recessed area when viewed dorsally or medioposteriorly (Figs. 152a, c, d; 153a, c); dorsal and ventral branches of paraproct subequal (Figs. 152b, 153b); middorsal thoracic stripe parallel (as in Fig. 42); sides of S8–9 marked with black (Fig. 67); SE Arizona in USA south through Oaxaca and Tamaulipas and Orizaba-Cordoba-Veracruz City region of Veracruz State in Mexico (Fig. 167) *extranea*
- 2'. Distal segment of genital ligula lacking a small digitiform appendage on its ental tip (Figs. 132a, c); cercus in medioposterior view with decumbent tooth at approximately basal 0.50 of margin (Figs. 151d, e, f), and with distal margin not produced into a tubercle, no shallow recessed area preceding this area (Figs. 151a, c, d); ventral branch of paraproct usually distinctly longer than upper branch (Fig. 151b); middorsal thoracic stripe usually constricted at base (as in Fig. 40); sides of S8–9 unmarked or mostly so (Figs. 63–66); Chiapas State and Los Tuxtlas region of S Veracruz State in Mexico south through Panama (Fig. 167) *elongata n. sp.*
- 3(1'). A low swollen transverse ridge on mesepisternum parallel to posterior margin of mesostigmal lobe extending from lateral tip of lobe to black antehumeral stripe; this ridge narrowly separated from lobe by a groove (Fig. 112c); base of mesostigmal lobe viewed ventrally lacking a transverse tubercle (Fig. 112e); middorsal thoracic stripe parallel (Fig. 42); SE Arizona in USA south through Oaxaca, Tamaulipas and Orizaba-Cordoba-Veracruz City region of Veracruz State in Mexico (Fig. 167) *extranea*
- 3'. No ridge on mesepisternum posterior to mesostigmal lobe (Fig. 111c); base of mesostigmal lobe viewed ventrally with a transverse tubercle (Fig. 111e); middorsal thoracic stripe usually constricted at base (Fig. 40); Chiapas State and Los Tuxtlas region of southern Veracruz State in Mexico south through Panama (Fig. 167) *elongata n. sp.*

Diagnostic characters of the genital ligula and of the placement of the decumbent tooth on the posterior margin of the cercus in males and morphology of the mesostigmal plates in females appear to be reliable diagnostic characters to recognize *A. elongata* and *A. extranea*. The relative length of ventral and dorsal branches of male paraproct and the constriction of the middorsal stripe are more variable and should not be used as the only means of distinguishing between these two species.

Remarks. Calvert (1902) commented on the variability of the paraproct length within *A. extranea*, noting a general increase in length north to south ("...In a general way, it seems that the relative and absolute length of the lower branch of the inferior appendage increases in specimens from north to south, i. e. in those from Mexico to Costa Rica...") and in 1907 ("....in the females [of *Argia extranea*] the black middorsal thoracic stripe is frequently narrowed at its lower end...."). Garrison (1994), in his account of *A. extranea*, discussed the details surrounding Calvert's (1902) broader concept of *A. extranea* and suggested that Calvert included an undescribed violaceous species from Texolo as well as noting the possibility that two species (*A. extranea* and *A. elongata* as treated here) might be involved. The more southerly populations (here treated as *A. elongata*) had long been recognized by the late L. K. Gloyd as separate from the more northerly *A. extranea*, for which she applied the manuscript name "extensa" to over 1,000 specimens she examined from numerous collections. Our treatment of this species confirms Gloyd's assertion that *A. elongata*, as treated here, is a closely related species but distinct from *A. extranea*.

Garrison (1994) listed *Argia mista* Navás as a junior synonym of *A. extranea* based on M. Westfall's examination of the holotype of *A. mista* at the MNHN. Through the kindness of Jean Legrand, we have been able to examine the holotype of *A. mista* (Fig. 153) as well as the holotype of *Agrion extraneum* Hagen (Figs. 151a–d) and can confirm their synonymy. Our distribution records of *Argia extranea* show it to occupy the foothills of the Sierra Madre Occidental, del Sur and Oriental; we have seen no records from the lowland areas bordering the Gulf of Mexico and we suggest that Saussure's 1854–5 collection of the holotype likely occurred further west than its stated type locality of Tampico.

Garrison and von Ellenrieder (2015) discussed the confused applications of the name *extranea* to various South American species described by Fraser (1946).

Habitat. Rocky to muddy rivers and streams and open areas near trickles and ponds, in primary forest to disturbed habitats. *Argia elongata* is the most common species of *Argia* to be found within its range. Specimens have been collected year round at various localities at elevations ranging from near sea level (Mexico: Agua Caliente) to over 2,000 m (Mexico: steep ridge above Siltepec on road to El Porvenir). This species is primarily an inhabitant of the moist foothills of the Sierra Madre Occidental, del Sur, and Oriental occurring at altitudes over 100 m. It appears to be absent from the central plateau (Altiplanicia Mexicana). Of over 300 localities recorded, only eight yielded collections under 100 m.

TABLE 4. Wing counts and measurements (average and standard deviation followed by range in square brackets) for various *Argia* species treated in this study.

TABLE 5. Estimates of Evolutionary Divergence between Sequences of dark and pale morphs of *Argia fulgida*. The number of base differences per sequence from between sequences are shown. Standard error estimate(s) are shown above the diagonal. The analysis involved 9 nucleotide sequences. All ambiguous positions were removed for each sequence pair. There were a total of 503 positions in the final dataset. Evolutionary analyses were conducted in MEGA5.

Distribution. *Argia elongata* shows an allopatric distribution with its close relative *A. extranea*, extending from Veracruz and Oaxaca states in S Mexico south to Panama (Fig. 167), while *A. extranea* extends from the Los Tuxtlas region of central Veracruz and Oaxaca states north to Arizona in SW USA (Fig. 167). Selys (1865) lists *A. extranea* from Colombia (probably by Nicholas Funck) and Surinam (by Robert H. Schomburgk), but we have seen no specimens of *A. elongata* from South America. The Colombian record, if by Funck, likely corresponds to incorrectly labeled specimens as to locality, as discussed by González-Soriano and von Ellenrieder (2009), and the specimen from Surinam is probably a misidentification (Belle 2002).

***Argia haberi* Garrison & von Ellenrieder, n. sp.**

Figs. 26 (head, thorax, S1–4 ♂); 75 (S7–10 ♂); 124 (wings); 140 (genital ligula); 160 (appendages ♂); 171 (map); Table 4 (measurements).

Etymology. Named ***haberi*** (Latinized name) in honor of our friend and colleague William A. Haber, in recognition to his valuable contributions to the knowledge of Costa Rican odonates and his generous help in our studies.

Specimens examined. 4 ♂. **Types.** Holotype ♂: COSTA RICA, San José Prov.: km 118 on Pan American highway, Bosque del Tolomuco, in seeps and trickles through brushy pasture on forested hillside (9°28'18" N, 83°41'48" W, 1710 m), 27 iii 2006, F. Sibley leg. [FSCA]. Paratypes: COSTA RICA, San José Prov.: 1 ♂, same data as holotype but [RWG]; 1 ♂, same data as holotype but [CSCA]; 1 ♂, same data as holotype but [TWD].

A medium-sized largely blue species with slightly amber wings (Fig. 124) and appendages (Fig. 160) superficially similar to those of *A. rhoadsii* Calvert (Fig. 161).

Description of male holotype. Head (Fig. 26): Labium blue lined with black at base and with a small black medial spot connected to basal black, anteclypeus blue; postclypeus blue margined with black at base and with a basal black spot mediolaterally extending from base; base of mandibles and genae blue, antefrons blue; remainder of epicranium black with the following blue: large postocular spot confluent with eye, small triangular spot anterolateral to lateral ocellus, a wash of light brown on posterior most margin of occiput; antennae black, rear of head except for narrow pale margin bordering eye entirely black.

Prothorax black with following areas pale: posterior margin of anterior lobe, dorsolateral spot on middle lobe, laterobasal 0.10 of posterior margin of pronotum, propleuron except for brown notopleural suture. Pale areas of pterothorax blue, with broad black middorsal stripe about three times as wide as pale antehumeral stripe, the latter narrowing dorsally; black humeral stripe extending from anterior half of mesinfraepisternum and constricted above and widening irregularly with a thick posterior fork at upper fourth, anterior portion of stripe narrow connecting below antealar crest with middorsal stripe above and with a short ventrally directed finger on dorsal portion of obsolete interpleural suture; interpleural suture with narrow black stripe separating paler areas on side of thorax (Fig. 26). Wings slightly amber (as in Fig. 124) with venation black; pterostigma dark brown, surmounting 1.5 cells in Fw, 2 cells in Hw; postnodals Fw 15/15, Hw 13/13; postquadrangular cells Fw 4/4, Hw 3/3; RP₂ at Fw 7/7, Hw 6/6. Coxae and trochanters pale except for wash of black on medial portions of coxae and dorsum of trochanters; internal 0.50 base surface of femora and external surface of tibiae pale, remainder of legs and armature black.

Abdomen (Figs. 26, 75) mostly black; S1 blue with a basal black ring at basal 0.50 and with black spot extending dorsally to apical 0.70; S2 black with a campanulate dorsal spot at basal 0.60, laterally with black separated below by blue, genital lobe slightly angulate, annulus black; S3 with distal 0.70 black, this receding above allowing for an extension of middorsal blue stripe ending at basal 0.40 of segment; S4–6 similar to S3 but basal blue further restricted basally; on S6, narrow upper offshoot of black at proximal 0.10 almost isolates dorsal blue, thus almost forming a middorsal spot; S7 black with a narrow blue ring; S8–9 blue except for narrow incomplete vertical black spot apically on intersegmental membrane on S8; S10 black, blue dorsally; torus pale, appendages black.

Genital ligula (Fig. 140) with apical segment spatulate broadening basally with short lateral sclerotized lobes, ental surface of genital ligula concave; small inner fold present, sclerotized portion proximal to flexure lacking a microspinulate patch on ental surface on each side.

Torus large, transversely oval, swollen ventrally, occupying 0.50 ventral margin of torifer and not overlapping bilobed epiproct (Fig. 160c); area around epiproct and base of same black; cercus (Figs. 160a, c) short, quadrangular, about half as long as paraproct (Fig. 160b), outer margin convex, slightly bilobed apically, medial

margin armed with a prominent decumbent tooth, slightly concave medially; medial margin linear, planate dorsomedially; paraproct unilobed, its ventral branch vestigial and much smaller than broadly triangular upper branch, its tip blunt, posterior margin linear.

Dimensions. Hw 22.9, abdomen 29.4, total length 37.7.

Female: Unknown.

Variation in paratypes. Little variation was observed in the series collected at the type locality. One male has reduced black on labrum; the other paratype has the black humeral stripe branched as in holotype but stripe is of uniform width medially. Pterostigma surmounting 1–2 cells; postnodals: Fw 15–16, Hw 13–14; postquadrigular cells Fw 4, Hw 3–4; RP₂ at Fw 7–8, Hw 6–7. **Dimensions.** ♂: Hw 22.9 ± 0.4 [22.5–23.3], abdomen 29.4 ± 1.0 [28.3–30.2], total length 37.6 ± 1.1 [36.8–38.4].

Diagnosis. Appendage morphology superficially resembles that of *A. rhoadsi* (Fig. 161), as both possess a quadrate cercus and a unilobate paraproct extending well beyond level of cercus. However, the decumbent tooth is not as prominent and is placed more basally in *A. rhoadsi* (Fig. 161) compared with *A. haberl* (Fig. 160). The torus in *A. rhoadsi* is more elongate and partially overlaps the epiproct (Fig. 161c), compared with the shorter non-overlapping torus in *A. haberl* (Fig. 160c). The greatest difference is in the morphology of the genital ligula: terminal segment rectangular with two flagella and small poorly developed lateral lobes at flexure in *A. rhoadsi* (Fig. 141) versus a spatulate terminal segment lacking flagella and with relatively larger lateral lobes in *A. haberl* (Fig. 140). Although males of both species possess amber-colored wings, the pale coloration in *A. rhoadsi* (Figs. 27, 76) is an aquamarine blue compared to a more intense violaceous blue in *A. haberl* (Figs. 26, 75).

Remarks. Despite superficially similarity between *A. haberl* and *A. rhoadsi*, these two species with entirely different genital ligula morphology are probably not closely related.

Habitat. The four males known were found along seeps and trickles through brushy pasture on a forested hillside.

Distribution. So far known only from its type locality in San José Prov., Costa Rica (Fig. 171).

Argia rudolphi Garrison & von Ellenrieder, n. sp.

Figs. 19 (head, thorax, S1–4 ♂); 43 (head, thorax, S1–4 ♀); 68 (S7–10 ♂); 92 (S7–10 ♀); 113 (mesostigmal plates ♀); 154 (appendages ♂); 168 (map); Table 2 (measurements).

Etymology. Named *rudolphi* (Latinized name) in honor of our colleague Rainer Rudolph, in recognition for his generous support of the International Dragonfly Fund, which has helped further the knowledge of Odonata worldwide over the past twenty years.

Specimens examined. 18 ♂, 5 ♀. **Types.** **Holotype** ♂: MEXICO, Puebla State, Zihuateutla, Sierra de Huauchinango, La Unión, in drainage area (20°14'25" N, 97°53'38" W, 596 m), 21 v 1987, R. Novelo & A. Gomez leg. [CSCA]. Paratypes: MEXICO, Hidalgo State: 6 ♂, 3 ♀, stream with cascade 7 km N of Tlanchinol (21°3'5" N, 98°40'4" W, 1,300 m), 21 vii 1992, G. Harp leg. [RWG]; 2 ♂, same data but 22–23 vii 1992, TWD leg. [RWG]; Puebla State: 1 ♂, Zihuateutla, Sierra de Huauchinango, km 3 road to. La Unión, Zona Cafetalera in drainage area (20°15'31" N, 97°52'5" W, 570 m), 23 vii 1987, R. Novelo leg. [CSCA]; 4 ♂, same data but [RWG]; 3 ♂, 1 ♀ (one pair in tandem), same data as holotype [RWG]; Veracruz State: 1 ♂, 1 ♀ (in tandem, female ovipositing), El Muro, km 14 on road 131 Tlapacoyan-Altotonga (19°52'41" N, 97°13'41" W, 1,100 m), 15 vii 2000, R. Novelo leg. [RWG].

A medium-sized largely violaceous-blue species (Figs. 19, 68, based on well-preserved material) with approximate cerci (Fig. 154) the male of which is similar to *A. anceps* (Figs. 20; 69; 181), *A. fissa* (Figs. 21; 70; 183) and *A. westfalli* (Figs. 22, 23, 71, 72).

Description of male holotype. Head (Fig. 19): Labium pale except for small black medial spot at base; ante- and postclypeus, antefrons, base of mandibles, anterior half of scape and genae pale, remainder of head black with violaceous postocular spots confluent with eyes, incomplete pale occipital bar and small pale spot anterolateral to lateral ocellus; posterior half of scape and remainder of antennae black, rear of head washed with black, especially medially, margin bordering eye margin pale.

Prothorax black with following areas pale: obscure lateral spot on anterior lobe, dorsolateral spot on middle lobe, lateral 0.30 of posterior margin of pronotum, propleuron except for notopleural suture. Pale areas of

pterothorax violaceous blue, with black middorsal stripe about as wide as pale antehumeral stripe, the latter slightly narrowing dorsally; anterior half of mesinfraepisternum black, continuous with broad humeral stripe at base, then narrowing at basal fifth along mesopleural suture, then abruptly forming a thin hairline at 0.50 before expanding again at mesopleural fossa and connecting narrowly below antealar crest with middorsal stripe above; metapleural suture with a narrow black stripe separating paler areas on side of thorax (Fig. 19). Wings hyaline with venation black; pterostigma dark brown, surmounting 2 cells in both Fw and 2 cells in left Hw [distal 0.80 of right Hw missing]; postnodals Fw 18/19, left Hw 16; postquadrangular cells Fw 4/4, left Hw 3; RP₂ at Fw 8/8, left Hw 6. Coxae and trochanters pale medially washed with brown; extensor surfaces of tibiae pale, remainder of legs and armature black.

Abdomen (Figs. 19, 68) mostly violaceous blue; S1 pale with narrow black basal ring expanding dorsally to form a connected black spot occupying basal 0.50; S2 pale above with an incomplete black lateral stripe widening posteriorly and ending at distal 0.30, this stripe connected to obscure black spot below thus isolating pale areas anteriorly and posteriorly, genital lobe not strongly produced, apical annulus black; S3 pale with an narrow lateral black stripe, apical 0.20 including annulus black except for small isolated transverse spot before annulus; S4 similar to S3 but with remnant of postbasal streak; S5 similar but postbasal streak more extensive with vestigial line connecting to apical black; S6 with postbasal black confluent with apical black thus forming a broad ventral stripe; S7 black except for narrow pale ring with a broad triangular extension middorsally ending at basal 0.20; S8–10 pale dorsolaterally and black ventrally; torus pale, cerci black; dorsal portion of paraprocts pale, ventrally black.

Genital ligula (Fig. 137) similar to *A. elongata* (as in Fig. 132) but tip narrower. Lateral lobes appressed to lateral margin of distal segment

Torus large, transversely triangular, swollen ventrally, occupying ventral half of torifer and overlapping recessed bilobed epiproct (Fig. 154c); narrow area around epiproct and extreme base of same black; cercus roughly quadrate in dorsal view with outer margin about 1.5 times as long as inner margin (Fig. 154c); in mediadorsal view upper surface slightly concave with a broadly based tooth at basal 0.20 (Fig. 154a, d); in lateral view, narrowly triangular, subequal to length of paraproct (Fig. 154b); paraproct slightly bilobed, its ventral branch much smaller than longer, anteriorly directed, bluntly triangular dorsal branch, its tip, viewed mediadorsally (Fig. 154a), directed medially.

Dimensions. Hw 21.5, abdomen 30, total length 37.5.

Description of female paratype (Mexico: Veracruz State, El Muro, km 14 on road 131 Tlapacoyan-Altotonga). Similar to male but pale color light blue. Head (Fig. 43) as in male but with a black basal spot mediolaterally on labrum and postocular spots larger and confluent with eye, prothorax as in male but black areas less extensive, pterothorax with humeral stripe narrower and more deeply forked; S1 as in male; S2 with dorsal oval spot at basal 0.60, apically and laterally with black interrupted below by a pale lateral stripe narrowed at apical 0.30, pale lateral stripe bordered below by a black stripe; S3 dorsally pale with apical 0.30 black, the latter with a ventral offshoot of black along ventral margin and expanding at basal 0.10 and almost connecting with an elongate postbasal streak, which is at first broad but narrows to a thin line just connecting with apical black; S4–5 similar to S3 but black more extensive, isolating a pale midlateral stripe; dorsal blue also reduced, especially apically, but with an incomplete pale basal ring; S6–7 black with an incomplete pale basal ring; S8 blue dorsally, black at basal 0.20 and laterally; S9 blue dorsally with a black dorsolateral spot at basal 0.50 and connected to lateral stripe below; S10 blue dorsally, black laterally; appendages and ovipositor black.

Mesostigmal lobe forming a broad oval (Fig. 113a, b), about twice as wide as high, occupying medial 0.60 of posterior margin of mesostigmal plate (Fig. 113c), medial margin thickened with a slightly recurved margin (Fig. 113d, e), and slightly overlying fork of middorsal carina; distance between mesostigmal lobes small, barely separated (Fig. 113a, c); in lateral view, lobe erect with posterior margin curving medioposteriorly (Fig. 113g).

Variation in paratypes. Little variation was observed in the paratype series. One male (Sierra de Huachinango) had a small indication of a forked humeral stripe; another male (same locality) had reduced black abdominal markings thus isolating black postbasal streaks on S4–5 similar to S4 in Fig. 19. The small lateral lobes on the genital ligula of the holotype (Fig. 137b) are adjacent to the sides of the ligula, but in paratypes they are usually separated basally as in *A. elongata* (Fig. 132b). Females can be blue (Fig. 43) or brown. Pterostigma surmounting 1–2 cells in males and females; postnodals: Fw 16–20 in males and females, Hw 12–18 in males, 15–17 in females; postquadrangular cells Fw 3–5, Hw 3–4 in males, Fw 4, Hw 3 in females; RP₂ at Fw 7–8, Hw 6–7 in males and females. **Dimensions.** ♂: Hw 23 ± 1.95 [20–24], abdomen 30.3 ± 1.69 [27.6–33.1], total length 38.4 ±

2.17 [35.4–41.9]; ♀: Hw 24.8 ± 1.74 [22.3–26.5], abdomen 29.4 ± 2.11 [28.6–31.3], total length 37.7 ± 2.73 [33.5–40.1].

Diagnosis. This species may be confused with three other largely blue species, two of which, *A. anceps* and *A. westfalli*, are sympatric with *A. rudolphi* (Fig. 168). The cerci in male *A. rudolphi* are more approximate, with their inner surfaces nearly touching in normal position (Fig. 154c); in both *A. anceps* (Fig. 155c) and *A. westfalli* (Fig. 157c), the cerci are widely separated by a gap subequal to the basal width of each cercus. In dorsomedial view, the cercus of *A. rudolphi* (Fig. 154d) is less elongate than in either *A. anceps* (Fig. 155d) or *A. westfalli* (Fig. 157d). The nearly approximate condition of the cerci in *A. rudolphi* (Fig. 154d) is similar to that of the more southerly (Costa Rica to Colombia) *A. fissa* Selys (Fig. 156c), but the transverse width of the torus in *A. fissa* (Fig. 156c) is subequal to the transverse width of each cercus; in *A. rudolphi* the transverse width of each torus is about half the transverse width of each cercus (Fig. 154c). The tip of the terminal segment of the genital ligula in *A. rudolphi* is short and narrow, ending in a more or less ridged trough-shaped tip (Fig. 137); the tip in the other three species is longer and flexible and can assume the shapes illustrated here (*A. anceps* Figs. 134–136; essentially the same for *A. fissa* and *A. westfalli*). The ectobasal portion of the terminal segment of the genital ligula in *A. anceps* (Fig. 134a, b), *A. fissa*, and *A. westfalli* has a prominent narrow mound-like lobe that is absent in *A. rudolphi* (Fig. 137a, b). The following field markings will also distinguish male *A. rudolphi* from *A. anceps*, *A. fissa* and *A. westfalli*: The black postbasal streaks (sometimes extensive) present on S4–6 in *A. rudolphi* (Fig. 19) are absent in *A. anceps* (Figs. 20; 181), *A. fissa* (Figs. 21; 183) and *A. westfalli* (Figs. 22, 23); the wings are hyaline in *A. rudolphi* and strongly tinged with yellow in *A. anceps*, *A. fissa* (Figs. 181–183) and *A. westfalli*; and the pale coloration is violaceous blue in *A. rudolphi* and vivid blue in *A. anceps*, *A. fissa* and *A. westfalli*.

The large erect oval mesostigmal plates in *A. rudolphi* (Fig. 113) are almost approximate and are similar only to those of *A. fissa* (Fig. 116) and, to a lesser extent, *A. westfalli* (Figs. 117, 118) and *A. anceps* (Figs. 114, 115). A transverse swollen tubercle is present at the base of the mesostigmal lobe in posterior view in *A. anceps* (Fig. 115e); no tubercle is present in *A. rudolphi* (Fig. 113e), *A. fissa* (Fig. 116e) or *A. westfalli* (Figs. 117e, 118e). In *A. rudolphi*, the medial margin of the mesostigmal lobe is swollen and slightly recurved (Fig. 113d, e); no such swollen area is present in *A. fissa* (Fig. 116e) or *A. westfalli* (Figs. 117e, 118e). In the field, females of *A. rudolphi* (Fig. 43) are easily distinguished from those of the other three species (Figs. 44–46; 181–183) by the overall more extensive dark markings on the head (mostly black epicranium), thorax (prominent middorsal and humeral stripes), and abdomen (postbasal streaks coupled with distal and ventral black); the other three species are almost immaculate, there being only vestiges of black on the epicranium, a thin middorsal thoracic stripe, a narrow to absent humeral stripe, and vestiges of a distal black spot laterally on abdominal segments. The ovipositor in *A. rudolphi* is black (Fig. 92), not pale as in the other three species (Figs. 93–95).

Habitat. Streams and drainage areas. Specimens were taken at elevations ranging from about 570 m (Sierra de Huauchinango) to 1,300 m (stream with cascade 7 km N of Tlanchinol). Specimens have been collected in May (Sierra de Huauchinango) and July (stream with cascade 7 km N of Tlanchinol).

Distribution. Limited to a small area in the Atlantic slope of central Mexico within Puebla, Hidalgo, and Veracruz states (Fig. 168), where it occurs in sympatry with *A. anceps* and *A. westfalli*.

[UMMZ]; Tungurahua Prov.: 1 ♂, Guamo Yacu (Agoyan), Río Pastaza watershed {1°24' S, 78°22' W, 1,700 m}, 9 xi 1935, W. Clarke-Macintyre leg. [UMMZ]; 1 ♂, 1 ♀, same data but [RWG]; Morona Santiago Prov.: 1 ♂, Mangosisa, Río Upano {2°31' S, 77°53' W, 708 m}, L. Gomez vendor [UMMZ].

A medium-sized largely dark species with strongly forcipate male appendages (Fig. 159).

Description of male holotype. Head: labrum pale rimmed with narrow line of black apically and basally, anteclypeus dark brown, base of mandibles, genae, postclypeus pale (purple), remainder of head black except for postocular spots and small pale spot anterolateral to lateral ocellus (as in Fig. 25); antennae black, rear of head black except for pale narrow margin bordering eye margin.

Prothorax black with following areas pale: obscure pale rim on anterior lobe, small dorsolateral spot on middle lobe, lateral 0.30 of posterior margin of propleuron. Pale areas of pterothorax purple, with broad black middorsal stripe about four times as wide as pale antehumeral stripe, the latter slightly narrowing dorsally; broad parallel black humeral stripe extending from base of mesinfraepisternum and connecting below antealar crest with middorsal stripe above and with dorsal portion of obsolete interpleural suture; metapleural stripe narrow; pale colors on side of thorax purple (as in Fig. 25). Wings hyaline with venation black; pterostigma dark brown, surmounting 1.5 cells in right Fw, 2 cells in left Fw; postnodals Fw; 2 cells in left Hw, 1.5 cells in right Hw; postnodals Fw 17/18, Hw 16/15; postquadrangular cells Fw 4/4, Hw 4/3; RP₂ at Fw 8.5/8.5, Hw 7/7. Coxae and trochanters pale except for black on ventral and anterior portions of coxae and dorsum of trochanters; femora, tibiae, tarsi and armature black.

Abdomen (as in Figs. 25, 74) mostly black; S1 with a black basal ring, remainder purple; S2 black with a pale (purple) dorsal campanulate spot occupying basal 0.80 of segment, abruptly narrowing to a thin line almost extending to black apical annulus, laterally black with a pale lateral stripe; S3 black except for narrow basal dorsal inverted triangular spot at basal 0.10; S4–5 similar to S3 but with only a small obscure pale dorsal spot at basal 0.05; S5–7 black; S8 with a dorsolateral pale (purple) spot interrupted basally by a narrow ring of black and posteriorly by black lateral stripe extending dorsally at apical 0.10; S9 pale dorsally, black laterally; S10 black with a pair of purple spots dorsally interrupted by narrow middorsal black stripe; torus pale, appendages black.

Genital ligula (Fig. 139) with a large elongate microspinulate patch on ental surface proximal to flexure on sclerotized area (Fig. 139d); distal segment lacking lateral sclerotized lobes and terminating in a single long curved flagellum.

Torus small, transversely oval, swollen, occupying entire ventral margin of torifer but not overlapping bilobed epiproct (Fig. 159a, c); area around epiproct and base of same black; cercus (Fig. 159a, c) long, about twice as long as paraproct (Fig. 159b), forcipate and ending in a capitate tooth; paraproct bilobed, its ventral branch much smaller than larger dorsal branch, in lateral view, dorsal branch bluntly triangular.

Dimensions. Hw 21.5, abdomen 28.4, total length 36.7.

Description of female paratype (Ecuador: Napo Prov., Cushillu-Yacu, Río Napo watershed, El Partidero). Head, pro- and pterothorax and S1–2 as in male (Fig. 50), but postocular spots and antehumeral stripe dull purple and pale colors on side of thorax olive brown; S1 as in male; S2 black dorsally with a narrow ventral pale stripe; S3–7 black with vestiges of narrow pale lateral stripe; S8 black with blue distal spot occupying apical 0.40; S9 black with posterior 0.50 blue extending laterally and projecting anteriorly to basal 0.30; S10 blue dorsally, black ventrally, cerci and ovipositor black (Fig. 97).

Mesostigmal lobe as in Fig. 120, well developed but small, forming a flat medially directed digit-like lobe elevated above mesepisternum and not overlying branch of middorsal carina; in posterior view (as in Fig. 120e) lobe thickened externally but lacking a tubercle at juncture with mesepisternum; mesepisternal tubercle absent.

Variation in paratypes. Little variation was observed in the paratype series. The dorsolateral spot on S10 in

male can range from present as in holotype to very small (El Partidero) or absent (Río Napo watershed). Pterostigma surmounting 1–2 cells in males, 1.5–2 in females; postnodals: Fw 16–18 in males, 16–17 in females, Hw 14–16 in males, 14–15 in females; postquadrangular cells Fw 3–5, Hw 3–4 in males, Fw 4–5, Hw 3–4 in females; RP₂ at Fw 7–9, Hw 6–7 in males, Fw 7–8, Hw 6–7 in females. **Dimensions.** ♂: Hw 20.9 ± 1.09 [19–22.3], abdomen 27.3 ± 1.22 [25.7–29.3], total length 35.2 ± 1.51 [33.3–37.8]; ♀: Hw 22.1 ± 1.45 [20.2–23.7], abdomen 27.2 ± 1.84 [25.3–29.4], total length 35.2 ± 2.08 [33.1–37.7].

Diagnosis. This species is superficially similar to *A. carolus* and is diagnosed under that species. Within its range (Ecuador), it is unlikely to be confused with any other species.

Habitat. Streams and rivers in forest. Specimens were taken at elevations ranging from about 400 m (Concepción-Río Napo) to 1,700 m (Guamo Yacu). Flight dates range from April (Headwaters of Río Arajuno) through December (Las Palmas, on Río Anzu).

Distribution. As far as known restricted to Ecuador east of the Andes (Fig. 169).

Argia schorri Garrison & von Ellenrieder, n. sp.

Figs. 28 (head, thorax, S1–3 ♂); 51 (head, thorax, S1–3 ♀); 77 (S7–10 ♂); 100 (S7–10 ♀), 101 (S1–5); 121 (mesostigmal plates ♀); 125 (wings); 142 (genital ligula); 162 (appendages ♂); 170 (map); 190 (field picture of ♀); Table 4 (measurements).

Etymology. Named *schorri* (Latinized name) in honor of our friend and colleague Martin Schorr, in recognition of his contributions to our knowledge of Odonata through the establishment of the International Dragonfly Fund, which has supported the research of countless odonatologists worldwide, his compilation of the Odonatological Abstract Service, and editing of the IDF-Reports for the past twenty years.

Specimens examined. 6 ♂, 1 ♀. **Types.** Holotype ♂: COSTA RICA, Puntarenas Prov.: 2.8 miles E of Golfito {8°39' N, 83°7' W, 35 m}, 4 vii 1967, O. S. Flint, Jr. & M. A. Ortiz B. leg. [USNM]. Paratypes: COSTA RICA, Puntarenas Prov.: 1 ♂, same data as holotype [USNM]; 1 ♂ same data as holotype but [RWG]; 1 ♂ same data as holotype but [CSCA]; 1 ♂, same data as holotype but [USNM]; 2 ♂, 1 ♀, 2 km NE of Uvita, Finca Carolina, Uvita Tropical Studies Institute, Río Ballena and small tributaries in primary and secondary forest (9°9'47" N, 83°42'49" W, 275 m), 15 xi 2010, W. Haber leg. [RWG].

A dark medium-sized species similar in male appendage morphology (Fig. 162) to *A. popoluca* (Figs. 163, 164).

Description of male holotype (colors poorly preserved). Head: Labium pale merging to black at basal half, ante- and postclypeus black, genae and base of mandibles pale, ante- and postfrons and anterior portion of scape pale, remainder of head black with purple postocular spots and small pale spot anterolateral to lateral ocellus; remainder of antennae black, rear of head black except for broad margin bordering eye.

Prothorax black with following areas pale: anterior lobe, dorsolateral spot on middle lobe, propleuron except for notopleural suture. Pale areas of pterothorax dark purple, with black middorsal stripe about as wide as pale antehumeral stripe, the latter gradually narrowing dorsally; black humeral stripe extending from base of mesinfraepisternum and connecting narrowly below antealar crest with middorsal stripe above and encompassing a small pale spot just below carina (similar to Fig. 28); interpleural suture with narrow black stripe separating paler areas on side of thorax (as in Fig. 28). Wings hyaline with venation black; pterostigma short, black, surmounting 1 cell in all wings (as in Fig. 125); postnodals Fw 12/12, Hw 11/11; postquadrangular cells Fw 3/3, Hw 3/3; RP₂ at Fw 7/7, Hw 5/5. Coxae and trochanters pale washed with black anterior portions of coxae; femora, tibiae, tarsi and armature black.

Abdomen (as in Figs. 28, 77) mostly black; S1 with a black basal ring, remainder purple; S1 blue with a narrow irregular black ring basally; S2 pale (purple) above with an irregular black lateral stripe ending just before black annulus, its anterior end connecting as a narrow black ring above, at apical 0.20 sending a narrow triangular offshoot dorsally but connecting above, ventrally with irregular pale stripe; S3–4 black laterally with pale basal ring and middorsal stripe ending at apical 0.20; S5–7 black with incomplete pale basal ring; S8–10 blue dorsally, black laterally (as in Fig. 77); torus pale, appendages black.

Genital ligula (Fig. 142) consisting of a long ridged flagellum, with a pair of entolaterally directed quadrate lobes at base.

Torus small, confined to ventral margin of torifer, the latter slightly triangularly concave, its base approximate to the opposite, and both completely overlapping bilobed epiproct (Fig. 162a, c); cercus (Fig. 162a, c) about twice as long as wide, rectangular, about subequal to paraproct, its tip slightly concave with a small partially hidden recurved tooth on medioapical margin; paraproct bilobed, its ventral branch much smaller than broadly triangular anteriorly directed dorsal branch (Fig. 162a, b).

Dimensions. Hw 19.4, abdomen 27, total length 34.4.

Description of female paratype (Costa Rica: Puntarenas Prov., 2 km NE of Uvita, Finca Carolina, Uvita Tropical Studies Institute, Fig. 190). Head similar to male but postocular spot not confluent to eye (Fig. 51); pro- and pterothorax and S1 as in male but antehumeral stripe brown and pale areas of pterothorax pale green (Fig. 51); S2 similar to male but with campanulate spot extending to apical 0.40; S3 with a blue basal ring and narrow blue middorsal stripe, apical 0.30 and laterally except for medial pale streak black (Figs. 51, 101); S4 similar but pale middorsal stripe narrower and pale mediolateral streak reduced; S5–7 black except for pale basal ring; S8 blue dorsally, black laterally; S9 narrowly blue dorsally with an offshoot of blue extending cephalad to medial 0.50, remainder black; S10 and ovipositor black (Fig. 100).

Mesostigmal lobe small, forming a raised recurved planar lobe arising laterally on lateral branch of carina just posterior to medial border of mesostigmal plate (Fig. 121d, c); lobe thickened when viewed posteriorly (Fig. 121e); a prominent mesepisternal tubercle medioposteriorly to mesostigmal lobe (Fig. 121b, c, e).

Variation in paratypes. Little variation was observed in the paratype series. The metapleural stripe in two males (2 km NE of Uvita, Fig. 28) is about 0.70 as thick as the humeral stripe. Pterostigma surmounting 1 cell in males and female; postnodals: Fw 12–14 in males, 13 in female, Hw 10–11 in males, 10 in female; postquadrangular cells Fw 3–5, Hw 3 in males, Fw 3, Hw 3 in female; RP₂ at Fw 6–8, Hw 5 in males, Fw 6–7, Hw 4 in female. **Dimensions.** ♂: Hw 18.8 ± 0.90 [17.6–20.3], abdomen 25.5 ± 1.11 [24–27], total length 32.7 ± 1.27 [31.1–34.2]; ♀: Hw 20.1, abdomen 25.3, total length 32.8.

Diagnosis. Species unique in the male by diminutive rim-like torus and adjacent torifer completely overlapping epiproct (Fig. 162a, c), and in the female by the placement of recurved mesostigmal lobe on lateral branch of middorsal carina. In addition, the genital ligula consisting of a long, ridged single flagellum and a pair of entolaterally directed quadrate lobes at base (Fig. 142) and the shortened pterostigma covering only one cell (Fig. 125) will easily serve to distinguish this species. The male appendages of *A. schorri* (Fig. 162) are superficially similar to those of *A. popoluca* (Figs. 163, 164), as well as its color pattern (Figs. 129; 188, 189). However, *A. popoluca* differs from *A. schorri* by its male tori broadly ovate, occupying the ventral half of the torifer and not overlapping the epiproct (Figs. 163a, c, 164a, c) and by its two long flagella united basally by a common stem, broadened laminate base and lack of a pair of entolaterally directed quadrate lobes at base of genital ligula (Figs. 143, 144). In the field, male *A. popoluca* have smaller postocular spots that are not confluent with the eye, and the pale middorsal stripes are more extensive, often attaining the apical 0.20 of S6 (Figs. 188, 189). In the female, the mesostigmal lobes occupy the medial 0.50 of the hind margin of the mesostigmal plate, and are large broadly upright foliate structures that are almost approximate. Most females of *A. popoluca* have mesostigmal lobes as shown in Fig. 123, but one female (Costa Rica: Braulio Carrillo National Park) has a strongly recurved lobe medially (Fig. 122c, d, e). It was collected with a male the appendages of which are typical for this species.

Argia popoluca is apparently a variable species. Calvert (1902) in his original description mentions four postquadrangular cells in the Fw, and most material we have examined from Mexico sustains Calvert's observation. Specimens from farther south generally have only three Fw postquadrangular cells. The extent of the middorsal blue stripe is also variable, extending for most of the dorsum on S3 variably through S7 (Figs. 188, 189)¹.

Remarks. The small series (including holotype) of four males from Golfito was apparently exposed to

1. Garrison *et al.* (2003) examined the syntypes of *Argia variata* Navás, 1935, stating that "...*A. variata* is a *bona fide* species in the [*A.*] *gerhardi* [Calvert, 1909]/*nigror* [Calvert, 1909] group." Further examination of specimens of *A. popoluca* from over its entire range show that South American material previously referable to *A. variata* do not significantly differ from Central American material currently going under the name of *A. popoluca*. The genital ligula morphology of *A. variata* is the same as for Central American specimens, and all specimens differ from species (including type material) previously included within the *A. gerhardi/kokama/nigror* complex. Correspondingly, we consider *Argia variata* Navás, 1935, to be a junior synonym of *A. popoluca* Calvert, 1902.

excessive heat, causing the wing membrane and entire body to become excessively shiny and the colors poorly preserved.

Habitat. Small trickles within primary and secondary forests. On 31 May 2013, we attempted to locate this species at its type locality (2.8 mi E of Golfito) but were unsuccessful, probably due to overcast weather and intermittent precipitation. The area consisted of a small shaded stream within shaded forest, and no Odonata were seen. Specimens have been collected at elevations ranging from about 35 m (2.8 mi E of Golfito) to 275 m (2 km NE of Uvita), ranging from July (2.8 mi E of Golfito) to November (2 km NE of Uvita). Haber noted the following for two males and female collected at Finca Carolina: "[male & female] Perched on shrubs in sunny spot on high bank of tiny trickle down steep hillside" and [male taken in] "Light gap on high bank of tiny forest trickle down steep hillside".

Distribution. Known so far only from the southern Pacific side of Costa Rica, where it is sympatric with its similar-looking congener *A. popoluca* (Fig. 170).

Acknowledgments

Our thanks go to the IDF for generously providing funds to aid in our study of the *Argia* species from Costa Rica, in particular to Martin Schorr, Wolfgang Schneider, and Rainer Rudolph, whose support and hard work kept IDF alive during the past twenty years. We also are indebted to Carlos Esquivel and Bill Haber, who during our field work in Costa Rica graciously accompanied us to the best collecting localities they know and shared their extraordinary expertise on the local fauna. We are most grateful to colleagues who kindly made available specimens for examination or provided information about types or other specimens under their care: Adolfo Cordero Rivera (Universidade de Vigo, Pontevedra, Spain), Sarah Degenhart (Vienna, Austria), Thomas W. Donnelly (Binghamton, NY), Carlos Esquivel (Universidad Nacional, Heredia, Costa Rica), William Haber (Costa Rica), Oliver S. Flint, Jr. (USNM), Jim Johnson (Vancouver, WA), William Mauffray (FSCA), Dennis R. Paulson (Seattle, WA), Mark O'Brien (UMMZ), Kenneth J. Tennessen (Wautoma, WI), Fred Sibley (Alpine, NY) and Enrique González Soriano (Universidad Autónoma de Mexico, Mexico). Douglas Danforth (Bisbee, AZ), Netta Smith and Dennis Paulson (Seattle), and William Haber (Monteverde) generously provided us with color scans and photos of species included in this paper. Sandy Upson shared localities for *A. extranea* that made our map more complete. Scott Kinnee (CDFA, Sacramento) kindly sequenced specimens for the molecular analysis. Dennis R. Paulson kindly reviewed the manuscript.
